

Carbon and water fluxes in mountain forest and grassland ecosystems from leaf to ecosystem level: effects of climate variability and management

Participants: CNR IBAF, ARPA, UNITUS

Bologna, 22 Maggio 2014

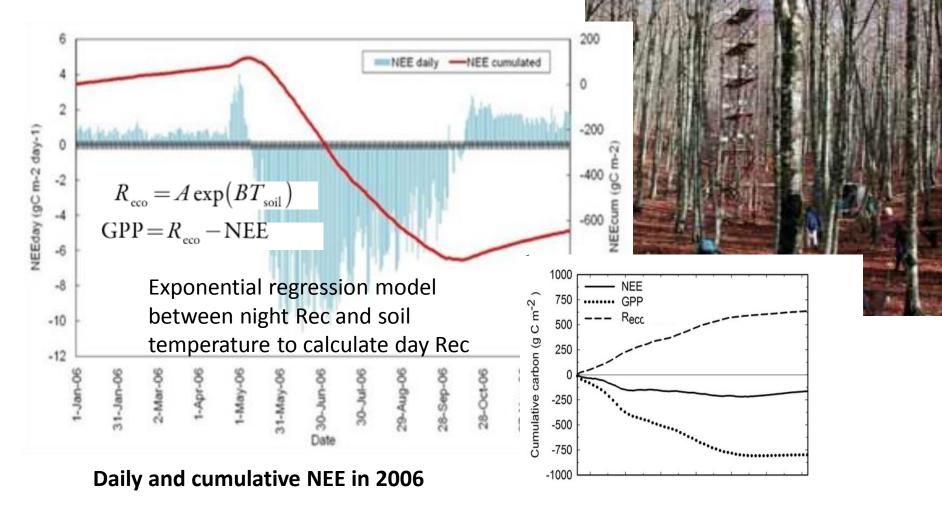

## **Objectives**:

- To bring together CO2, H2O and CH4 eddy fluxes from a number of long-term eddy covariance stations located in Alpine and Apennine forest and grassland ecosystems:
  - consolidation of an on-going network of mountain eddy covariance stations
    - harmonization of the already available data
      - definition of a common protocol
      - performing of new measurements
  - To perform new research activities on some aspects of mountain ecosystem functioning under changing climate and anthropic pressure.

**Modeling:** The data could be utilized for validation and tuning of global climate models, mesoscale and weather models, biogeochemical and ecological models, and remote sensing estimates from satellites and aircraft.

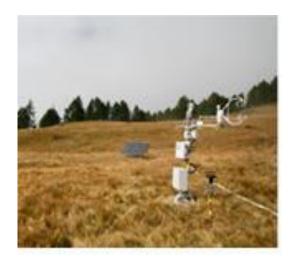

# **Collelongo**

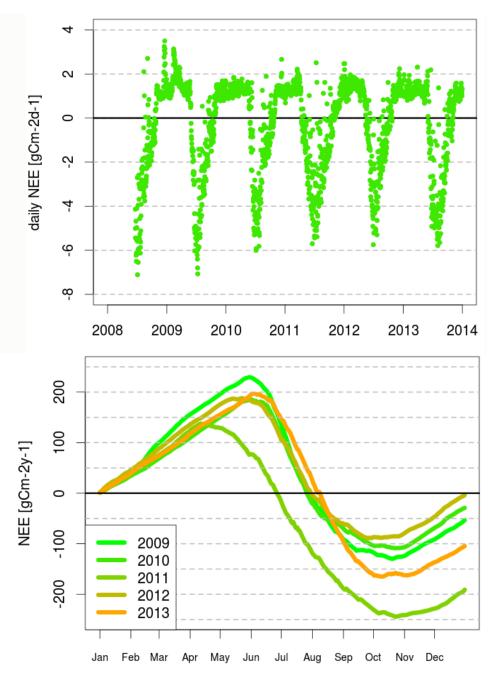

Fagus sylvatica Height 1700m asl Appenine chain Eddy flux since 1993 Auxiliary measurements Functional studies

#### Torgnon:

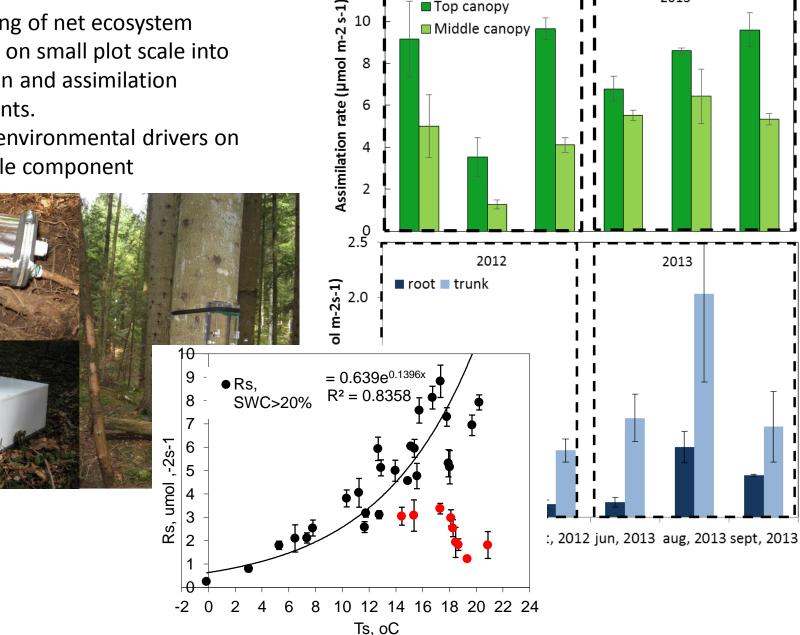

Abandoned grassland Height 2100m asl, West Alps Eddy flux since 2008 Automated soil respiration flux since 2009 Auxiliary measurements

### **Functional studies:**

- Partitioning of net ecosystem exchange on small plot scale into respiration and assimilation components.
- Effect of environmental drivers on each single component

2013

Compound analyses and stable isotopes to study C allocation patterns within the ecosystem
 Bud break
 Leaf shedding
 Bud break
 Leaf shedding

Seasonal variations in radial growth and wood carbohydrates content in the trunk

Isotopes as proxy for allocation changes(?): Trunk and root respiration are fuelled by the soluble sugars transported with the phloem during the growing period and by other sources (reserves) when the allocation changes from growth to accumulation.

# MULTISPECTRAL RADIOMETER SYSTEM MSR16R (CROPSCAN, Inc.)

The **CROPSCAN** multispectral radiometer MSR16R will allow us to collect continuous canopy reflectance measurements and compute several <u>reflectance indices</u>.

**Expected results:** 

- find a good correlation between NDVI and green fAPAR
  in order to use NDVI measurements as proxy of fAPAR
  in LUE model for ecosystem productivity calculations.
- observe that NDVI tracks changes in NEE throughout the season

work on the validation and comparison between remote sensing and ecophysiological parameters possibly related to gas exchange or environmental stress.
